Amortized Analysis

The time required to perform a sequence of (data structure) operations is averaged over all the operations performed.

No probabilistic assumptions - not an average case analysis!
Stack Operations

Push(S, x) - Push x to the stack S.

Pop(S, x) - Pop the top of stack S.

Multipop(S, k)

1. While not empty and k \neq 0 do
   1.1 Pop(S);
   1.2 k \leftarrow k - 1;

A call to Multipop(S, k) takes \( O(k) \) time.

A “naive” analysis of a sequence of \( n \) operations Push, Pop, and Multipop on an empty stack give \( O(n^2) \), since the worst case time of one stack operation is \( O(n) \).
Binary Counter

$k$ bit binary counter $A[0, \ldots, k-1]$.

$k = length[A]$

$x = \sum_{i=0}^{k-1} A[i]2^i$

Increment($A$):

1. $i \leftarrow 0$;

2. While $i < length[A]$ and $A[i] = 1$ do
   
   2.1 $A[i] \leftarrow 0$
   
   2.2 $i \leftarrow i + 1$

3. If $i < length[A]$ then $A[i] \leftarrow 1$.

What’s the cost of $n$ increments?

A worst case increment takes $O(k)$ steps, thus $O(nk)$ time.
Amortized Analysis - The Aggregate Method

Compute $T(n)$, the total work in $n$ operations and take $T(n)/n$.

Example #1: **Stack Operations:** The total amount of work is $O$(number of Push operations), thus $T(n) = O(n)$, and amortized work is $O(1)$.

Example #2: **Counter increments:** In $n$ increments the $i$-th bit ($i = 0, 1, ..., k - 1$) is flipped only every $2^i$ increments. Thus

$$T(n) = \sum_{i=0}^{\log n} \left\lfloor \frac{n}{2^i} \right\rfloor \leq n \sum_{i=0}^{\infty} \frac{1}{2^i} = 2n$$

Thus, the amortized work is $T(n)/n = O(1)$. 
Amortized Analysis - The Accounting Method

We associate a charge with each operation with the invariant that at any step the total charges in the new accounting is not smaller than the total real cost up to that point.

**Example #1: Stack Operations:**

Real cost: Push = 1; Pop = 1; \( \text{Multipop}(k, S) = \min(k, s) \).

Amortized charge: Push = 2; Pop = 0; \( \text{Multipop}(k, S) = 0 \).

Since the number of Pops is bounded by the number of Push operations, the total new charge at any given time is never smaller than the real cost.

A simple \( O(n) \) bound on the total amortized cost.
Example #2:

Counter increments:

Amortized charge: 2 for each flip to 1, 0 otherwise.

Since we start with all bits set to 0, this gives an upper bound on the real cost.

In each increment operation only one bit is flipped to 1 - $O(1)$ amortized cost.
**Amortized Analysis - The Potential Method**

Let $D_0$ be the initial data structure.

Consider a set of $n$ operations: $c_i$ the cost of operation $i$, $D_i$ the data structure after operation $i$.

The **potential function**:

$$\Phi : \{D_i \mid i = 0, \ldots, n\} \rightarrow R$$

The amortized cost of operation $i$ is

$$A(c_i) = c_i + \Phi(D_i) - \Phi(D_{i-1})$$
The total amortized cost:

\[
\sum_{i=1}^{n} A(c_i) = \sum_{i=1}^{n} (c_i + \Phi(D_i) - \Phi(D_{i-1}))
\]

\[
= \sum_{i=1}^{n} c_i + \Phi(D_n) - \Phi(D_0)
\]

If we can show that \(\Phi(D_i) \geq \Phi(D_0)\) for all \(i\), then

\[
\sum_{i=1}^{n} A(c_i) \geq \sum_{i=1}^{n} c_i
\]
Stack Operations

Real cost: Push = 1; Pop = 1; Multipop$(k, S) = \min(k, s)$.

Amortized charge: Push = 2; Pop = 0; Multipop$(k, S) = 0$.

Define $\Phi(D_i) =$ number of items in the stack.

$\Phi(D_i) \geq \Phi(D_0) = 0$.

The amortized cost of a push operation (starting with $s$ items in the stack) is:

$$A(c_i) = 1 + (s + 1) - s = 2$$

The amortized cost of a Multipop$(S, k)$ ($k' = \min(k, s)$)

$$A(c_i) = k' + (s - k') - s = 0$$

Thus, all operations have amortized cost $O(1)$, the total cost of $n$ operations is $O(n)$. 
Counter Increment

Amortized charge: 2 for each flip to 1, 0 otherwise.

Let $\Phi(D_i) =$ number of 1’s in the counter.

If counter starts with 0: $\Phi(D_i) \geq \Phi(D_0) = 0$.

Assume that the $i$-th operation (increment) flipped $t_i$ bits to 0.

The total cost of that operation is $t_i + 1$.

\[
A(c_i) = c_i + \Phi(D_i) - \Phi(D_{i-1}) = t_i + 1 + 1 - t_i = 2.
\]

The total amortized cost of $n$ operations is $O(n)$. 
If the counter didn’t start with 0:

\[
\sum_{i=1}^{n} A(c_i) = \sum_{i=1}^{n} \left( c_i + \Phi(D_i) - \Phi(D_{i-1}) \right)
\]

\[
= \sum_{i=1}^{n} c_i + \Phi(D_n) - \Phi(D_0)
\]

or

\[
\sum_{i=1}^{n} c_i = \sum_{i=1}^{n} A(c_i) + \Phi(D_0) - \Phi(D_n)
\]

\[
\leq \sum_{i=1}^{n} A(c_i) + k
\]
Dynamic Tables

Allocate storage to a table dynamically. When the allocated space is full, it is expanded by allocating more space, when large part of the space is empty the space allocated to the table shrinks.

Table-Insert - add one item to the table.

Table-Delete - delete a given item from the table.

We analyze a heuristics that uses space allocations in powers of 2.

\[
size[T] = \text{current size of the table.}
\]

\[
um[T] = \text{number of items currently in the table.}
\]

Initially \(size[T] = num[T] = 0\).

The cost of expanding/contraction of the table equal the number of elements in the table at the time of the operation.
Potential Function Analysis for Expansion Only

Double the size of the table when inserting to a full table.

The cost of expanding the table equal the number of elements in the table at the time of expansion.

\[ \Phi(T) = 2 \cdot num[T] - size[T] \]

\[ \Phi(T) = 0 \] initially, and right after expansions.

Since at least half of the table is always full \( \Phi(T) \geq 0 \).
Using Potential Function: \[ \Phi(T) = 2 \cdot \text{num}[T] - \text{size}[T] \]

Let \( \text{num}_i \), \( \text{size}_i \) and \( \Phi_i \) be the values after the \( i \)-th operation:

If the \( i \)-th step doesn't trigger an expansion;
\[
\text{num}_{i-1} = \text{num}_i - 1 \quad \text{and} \quad \text{size}_i = \text{size}_{i-1}
\]

\[
A(c_i) = c_i + \Phi_i - \Phi_{i-1}
\]
\[
= 1 + (2\text{num}_i - \text{size}_i) - (2\text{num}_{i-1} - \text{size}_{i-1})
\]
\[
= 1 + (2\text{num}_i - \text{size}_i) - (2(\text{num}_i - 1) - \text{size}_{i-1})
\]
\[
= 3
\]
Using Potential Function: $\Phi(T) = 2 \cdot num[T] - size[T]$

If the $i$-th step triggers an expansion;

$size_{i-1} = (num_i - 1)$

$num_{i-1} = num_i - 1 \text{ and } size_i = 2 \cdot size_{i-1} = 2(num_i - 1)$

$A(c_i) = c_i + \Phi_i - \Phi_{i-1}$

$= num_i + (2num_i - size_i) - (2num_{i-1} - size_{i-1})$

$= num_i + (2num_i - 2(num_i - 1))$

$= 3$

Thus the amortized work per step is $O(1)$. 
Potential Function Analysis for Expansion and Contraction

Let $\alpha(T) = \frac{num[T]}{size[T]}$.

Double the size of the table when inserting to a full table ($\alpha[T] = 1$), halve the table size when $\alpha[T] < 1/4$.

$$\Phi(T) = \begin{cases} 2num[T] - size[T] & \text{if } \alpha(T) \geq 1/2 \\ size[T]/2 - num[T] & \text{if } \alpha(T) < 1/2 \end{cases}$$

$\Phi(T) \geq 0$.

Let $\alpha_i$ be the value of $\alpha[T]$ after operation $i$. 
\[ \alpha(T) = \frac{num[T]}{size[T]} \]

Using Potential Function:

\[ \Phi(T) = \begin{cases} 
2num[T] - size[T] & \text{if } \alpha(T) \geq 1/2 \\ 
size[T]/2 - num[T] & \text{if } \alpha(T) < 1/2 
\end{cases} \]

**Table-Insert**

If \( \alpha_{i-1} \geq 1/2 \) then as before \( A(c_i) = 3 \).

If \( \alpha_{i-1} < 1/2 \) AND \( \alpha_i < 1/2 \)

\[ \text{num}_{i-1} = \text{num}_i - 1 \] and \( \text{size}_i = \text{size}_{i-1} \)

\[
A(c_i) = c_i + \Phi_i - \Phi_{i-1} \\
= 1 + (\text{size}_i/2 - \text{num}_i) - (\text{size}_{i-1}/2 - \text{num}_{i-1}) \\
= 1 + (\text{size}_i/2 - \text{num}_i) - (\text{size}_i/2 - (\text{num}_i - 1)) \\
= 0 \]
If $\alpha_{i-1} < 1/2$ AND $\alpha_i \geq 1/2$

\[\begin{align*}
num_{i-1} &= num_i - 1 \quad \text{and} \quad size_i = size_{i-1} \\
A(c_i) &= \phi_i - \phi_{i-1} \\
&= 1 + (2num_i - size_i) - (size_{i-1}/2 - num_{i-1}) \\
&= 1 + (2(num_{i-1} + 1) - size_{i-1}) \\
&\quad - (size_{i-1}/2 - num_{i-1}) \\
&= 3num_{i-1} - \frac{3}{2}size_{i-1} + 3 \\
&= 3\alpha_{i-1}size_{i-1} - \frac{3}{2}size_{i-1} + 3 \\
&< 3 \quad \alpha_{i-1} = num_{i-1}/size_{i-1} < 1
\end{align*}\]

Thus, amortized cost of Table-Insert is $O(1)$.
\[ \alpha(T) = \frac{\text{num}[T]}{\text{size}[T]} \]

Using Potential Function: \( \Phi(T) = \begin{cases} 
2\text{num}[T] - \text{size}[T] & \text{if } \alpha(T) \geq 1/2 \\
\text{size}[T]/2 - \text{num}[T] & \text{if } \alpha(T) < 1/2 
\end{cases} \)

**Table-Delete**

\( \text{num}_i = \text{num}_{i-1} - 1 \), and if \( \alpha_{i-1} < 1/2 \) there might be a contraction.

If there is no contraction: \( \text{size}_i = \text{size}_{i-1} \)

\[
A(c_i) = c_i + \Phi_i - \Phi_{i-1} = 1 + \left( \frac{\text{size}_i}{2} - \text{num}_i \right) - \left( \frac{\text{size}_{i-1}}{2} - \text{num}_{i-1} \right) = 1 + \left( \frac{\text{size}_i}{2} - \text{num}_i \right) - \left( \frac{\text{size}_i}{2} - (\text{num}_i + 1) \right) = 2
\]
\[ \alpha(T) = \frac{\text{num}[T]}{\text{size}[T]} \]

Using Potential Function: \[ \Phi(T) = \begin{cases} 
2 \text{num}[T] - \text{size}[T] & \text{if } \alpha(T) \geq 1/2 \\
\text{size}[T]/2 - \text{num}[T] & \text{if } \alpha(T) < 1/2
\end{cases} \]

\[ \text{size}_i = \text{size}_{i-1}/2 \]

If there is a contraction, \( c_i = \text{num}_i + 1 \), and
\[ \text{size}_i/2 = \text{size}_{i-1}/4 = \text{num}_i + 1. \]

\[
\begin{align*}
A(c_i) & = c_i + \Phi_i - \Phi_{i-1} \\
& = (\text{num}_i + 1) + (\text{size}_i/2 - \text{num}_i) \\
& \quad - (\text{size}_{i-1}/2 - \text{num}_{i-1}) \\
& = (\text{num}_i + 1) + ((\text{num}_i + 1) - \text{num}_i) \\
& \quad - ((2\text{num}_i + 2) - (\text{num}_i + 1)) \\
& = 1
\end{align*}
\]

If \( \alpha_i > 1/2 \) no contraction.

In all cases \( A(c_i) = O(1). \)
